Day 11 Assignment

Description:

This project extends the **BookVerse React application** by introducing form handling and structured state management to allow administrators to add new books to the collection. A book submission form is implemented using **Formik**, with input validation handled through **Yup** to ensure required fields such as title, author, and price are correctly entered.

The application implements the **Flux architecture** using Actions, Dispatcher, and Store to manage a unidirectional data flow. When a new book is submitted, the data is sent to the backend using **Axios** and the centralized store updates the application state. The Home page then reflects the newly added book instantly without reloading, demonstrating **Single Page Application (SPA)** behavior.

All existing features from the previous assignment, including book listing, search functionality, page navigation, and author details, remain intact while integrating the Flux-based data management system.

Objective:

The primary objectives of this assignment were:

- To implement form handling using Formik
- To validate user input using Yup validation schemas
- To implement the Flux architecture pattern using Actions, Dispatcher, and Store
- To demonstrate dependency injection for modular store management
- To update the application state dynamically when a new book is added
- To integrate frontend form submission with a backend using Axios and json-server
- To maintain smooth SPA navigation without page reloads
- To structure the application using modular and reusable React components
